CSCI 544 — Homework 2

Neural Networks for Sentiment Analysis

Python Version: 3.12.3 | **Framework:** PyTorch | **Dataset:** Amazon US Office Products Reviews

---

Overview

This notebook implements a complete NLP pipeline for sentiment analysis on Amazon product reviews, progressing from classical feature engineering to deep neural architectures:

Section	Topic
Q1	Dataset generation — loading, balancing, and labeling 250,000 reviews
Q2	Word embeddings — comparing pretrained vs. custom-trained Word2Vec
Q3	Baseline classifiers — Perceptron and SVM with averaged Word2Vec features
Q4	Feed-Forward Neural Networks — averaged and concatenated vector inputs
Q5	Convolutional Neural Networks — sequential word embedding inputs

Sentiment Classes:

- **Positive** (★★★★–★★★★★) — ratings 4–5
- **Negative** (★–★★) — ratings 1–2
- **Neutral** (★★★) — rating 3

Question 1: Dataset Generation

This section loads the raw Amazon US Office Products review dataset and prepares a balanced, labeled corpus for sentiment analysis.

Dataset: Amazon US Office Products Reviews (`amazon_reviews_us_Office_Products_v1_00.tsv.gz`)

Goal: Construct a balanced dataset of **250,000 reviews** with three sentiment classes derived from star ratings.

Dataset Preparation

The raw TSV file contains many metadata columns. We keep only two columns relevant to our task: `review_body` (the raw text of the review) and `star_rating` (integer rating from 1 to 5). Rows with missing values in either column are dropped before further processing.

Read Data

Load the compressed TSV dataset using `pandas`. The file is read with `on_bad_lines='skip'` to handle any malformed rows gracefully.

```
df = pd.read_csv(r'data/amazon_reviews_us_Office_Products_v1_00.tsv.gz', sep='\t', on_bad_lines='skip', low_memory=False)
```

```
df.shape
```

```
(2640254, 15)
```

```
df.head(3)
```

	marketplace	customer_id	review_id	product_id	product_parent	product_title	product_category	star_rating	help
0	US	43081963	R18RVCKGH1SSI9	B001BM2MAC	307809868	Scotch Cushion Wrap 7961, 12 Inches x 100 Feet	Office Products	5	
1	US	10951564	R3L4L6LW1PUOFY	B00DZYEXPQ	75004341	Dust-Off Compressed Gas Duster, Pack of 4	Office Products	5	
2	US	21143145	R2J8AWXWTDX2TF	B00RTMUHDW	529689027	Amram Tagger Standard Tag Attaching Tagging Gu...	Office Products	5	

Keep Reviews and Ratings

Select only the `review_body` and `star_rating` columns. The `star_rating` column is coerced to numeric (some values may be stored as strings), and rows with `NaN` values in either column are dropped to ensure data quality.

```
df.columns
```

```
Index(['marketplace', 'customer_id', 'review_id', 'product_id',
       'product_parent', 'product_title', 'product_category', 'star_rating',
       'helpful_votes', 'total_votes', 'vine', 'verified_purchase',
       'review_headline', 'review_body', 'review_date'],
      dtype='str')
```

```
print(df['star_rating'].dtype)
print(df['star_rating'].unique())
```

```
str

['5', '1', '4', '2', '3', '2015-06-05', '2015-02-11', nan, '2014-02-14']
Length: 9, dtype: str
```

```
df['star_rating'] = pd.to_numeric(df['star_rating'], errors='coerce')
print(df['star_rating'].dtype)
print(df['star_rating'].unique())
```

```
float64
[ 5.  1.  4.  2.  3. nan]
```

```
df.dropna(subset=['review_body', 'star_rating'], inplace=True)
```

```
df.shape
```

```
(2640080, 15)
```

```
df = df[['review_body', 'star_rating']]  # selecting only relevant columns
print(df.head(3))
print(df['star_rating'].value_counts().sort_index())  # checking distribution of classes
```

```
                                        review_body  star_rating
0                                     Great product.          5.0
1  What's to say about this commodity item except...          5.0
2    Haven't used yet, but I am sure I will like it.          5.0
star_rating
1.0     306967
2.0     138381
3.0     193680
4.0     418348
5.0    1582704
Name: count, dtype: int64
```

Relabeling and Sampling

Balancing: To prevent class imbalance from skewing model training, we sample exactly **50,000 reviews per star rating** (1–5), yielding a total of **250,000 reviews**.

Ternary Labeling: Star ratings are mapped to three sentiment classes:

Label	Sentiment	Star Ratings
1	Positive	★★★★ (4), ★★★★★ (5)
2	Negative	★ (1), ★★ (2)
3	Neutral	★★★ (3)

This mapping ensures clear semantic separation between classes while keeping neutral reviews as a distinct third class.

```
balanced_dfs = []

for rating in [1, 2, 3, 4, 5]:
    rating_df = df[df['star_rating'] == rating]

    if len(rating_df) >= 50000:
        sampled = rating_df.sample(n=50000, random_state=RANDOM_STATE)
    else:
        print(f"Warning: Only {len(rating_df)} reviews available for rating {rating}")
        sampled = rating_df

    balanced_dfs.append(sampled)
    print(f"Rating {rating}: {len(sampled)} reviews sampled")
```

```
Rating 1: 50000 reviews sampled
Rating 2: 50000 reviews sampled
Rating 3: 50000 reviews sampled
Rating 4: 50000 reviews sampled
Rating 5: 50000 reviews sampled
```

```
# Concatenate all
df_balanced = pd.concat(balanced_dfs, ignore_index=True)

2    100000
3     50000
Name: count, dtype: int64
```

Data Cleaning

Raw review text contains substantial noise that can degrade NLP model performance. A systematic text cleaning pipeline is applied to normalize the reviews before further processing.

Cleaning steps (in order):

1. **Lowercase** — Normalize all text to lowercase to reduce vocabulary size.
2. **HTML removal** — Strip HTML tags (e.g., `<br>`, `<b>`) using `BeautifulSoup`.
3. **URL removal** — Remove `http://`, `https://`, and `www.*` links via regex.
4. **Contraction expansion** — Replace contractions with their full forms (e.g., *can't* → *cannot*, *I'm* → *I am*) using a hand-crafted mapping of 90+ contractions.
5. **Special character removal** — Retain only alphanumeric characters and whitespace.

Average review character length is measured before and after cleaning to quantify the effect of each step.

Pre-processing

After data cleaning we apply standard NLP preprocessing to reduce vocabulary size and normalize token forms. Two operations are performed in sequence:

1. **Stop-word removal** — High-frequency function words (*the*, *is*, *and*, etc.) are removed using NLTK's English stop-word list. Negation words (`not`, `no`, `never`, `neither`, etc.) are explicitly **preserved** because they carry critical sentiment polarity information.
2. **POS-aware Lemmatization** — Each token is reduced to its base (lemma) form using NLTK's `WordNetLemmatizer`. Part-of-speech tags from Penn Treebank (`pos_tag`) are mapped to WordNet POS constants (ADJ, VERB, NOUN, ADV) to select the correct lemma (e.g., *running* → *run*, *better* → *good*).

Average review length is logged before and after each step to quantify vocabulary reduction.

```
from nltk import pos_tag
from nltk.corpus import wordnet

def get_wordnet_pos(treebank_tag):
    """Convert treebank POS tags to WordNet POS tags"""
    if treebank_tag.startswith('J'):
```

```
        return wordnet.ADJ
    elif treebank_tag.startswith('V'):
        return wordnet.VERB
    elif treebank_tag.startswith('N'):
        return wordnet.NOUN
    elif treebank_tag.startswith('R'):
        return wordnet.ADV
    else:
        return wordnet.NOUN  # default to noun
```

```
from nltk.stem import WordNetLemmatizer
def lemmatize_with_pos(text):
    """
    Enhanced lemmatization that tries multiple POS tags for better results
    """
    lemmatizer = WordNetLemmatizer()
    words = text.split()

    if not words:
        return ""

    # POS tag the available text
    pos_tags = pos_tag(words)

    lemmatized = []
    for word, pos in pos_tags:
        # Get primary WordNet POS
        primary_pos = get_wordnet_pos(pos)

        # Try lemmatizing with the detected POS
        lemmatized_word = lemmatizer.lemmatize(word, primary_pos)

        # If word didn't change and it might be a verb, try verb lemmatization
        if lemmatized_word == word and primary_pos != wordnet.VERB:
            verb_form = lemmatizer.lemmatize(word, wordnet.VERB)
            # Use verb form if it's different (likely was actually a verb)
            if verb_form != word:
                lemmatized_word = verb_form

        lemmatized.append(lemmatized_word)

    return ' '.join(lemmatized)
```

Stop-Word Removal

Common function words (*the, is, at, which, on*, etc.) are removed because they carry little semantic meaning for sentiment classification. Negation words — a subset of stop words — are **intentionally kept** since they directly flip the polarity of adjacent sentiment words (e.g., *not good ≠ good*).

```
from nltk.corpus import stopwords

def remove_stopwords(text):
    """Remove stopwords but keep negation words"""
    stop_words = set(stopwords.words('english'))

    # CRITICAL: Keep negation words for sentiment analysis
    negations = {
        'no', 'not', 'nor', 'never', 'neither', 'nobody', 'nothing',
        'nowhere', 'none', 'hardly', 'scarcely', 'barely'
    }
    # Remove negation words from stopwords list
    stop_words = stop_words - negations

    words = text.split()
    filtered = [word for word in words if word not in stop_words]
    return ' '.join(filtered)

# Test it on a sample
sample_text = "this is not a good product and i do not recommend it"
print("Original:", sample_text)
print("After stopword removal:", remove_stopwords(sample_text))
# Should keep "not" in the output
```

```

Lemmatization

Lemmatization maps inflected word forms to their canonical base form (lemma), reducing vocabulary size without losing semantic information. Unlike stemming (which chops word suffixes heuristically), lemmatization uses linguistic knowledge:

- *running* → *run* (verb)
- *better* → *good* (adjective)
- *products* → *product* (noun)

We use **POS-aware lemmatization**: each word is first POS-tagged using Penn Treebank tags (`pos_tag`), then the tag is converted to a WordNet POS constant so the lemmatizer selects the morphologically correct base form.

```
#save before lemmatization
samples_before_lemmatization = df_balanced['review_body'].head(3).copy()

```

Question 2: Word Embeddings

Word2Vec represents each word as a dense, fixed-size vector in a continuous vector space where semantically similar words are placed close together. We evaluate two sources of 300-dimensional embeddings:

Model	Source	Vocabulary	Training Corpus
Pretrained	`word2vec-google-news-300`	~3 million words	~100 billion words (Google News)
Custom	Trained on our dataset	~domain-specific	250,000 Amazon Office Product reviews

We compare both models across vocabulary coverage, out-of-vocabulary (OOV) rate, domain-specific similarity, and semantic analogy quality to determine which better represents our review data.

(a) Pretrained Word2Vec — `word2vec-google-news-300`

We load Google's publicly available pretrained Word2Vec model via Gensim's downloader API. This model was trained on approximately **100 billion words** of Google News text using the **Skip-gram** architecture, producing 300-dimensional vectors for ~3 million vocabulary entries.

We verify the model with two semantic tests:

- **Analogy test:** *king − man + woman ≈ queen* (classic semantic arithmetic)
- **Similarity test:** cosine similarity between domain-relevant word pairs (e.g., *excellent ~ outstanding*)

```
pretrained_w2v = api.load('word2vec-google-news-300')
```

```
print(f"Vocabulary size: {len(pretrained_w2v.key_to_index):,}")
print(f"Vector dimensionality: {pretrained_w2v.vector_size}")
```

```
Vocabulary size: 3,000,000
Vector dimensionality: 300
```

```
# SEMANTIC SIMILARITY TEST 1: King - Man + Woman
try:
    result = pretrained_w2v.most_similar(
        positive=['king', 'woman'],
        negative=['man'],
        topn=5
    )
    print("\nTop 5 results:")
    for word, score in result:
        print(f"  {word:15} similarity: {score:.4f}")
```

```
except KeyError as e:
    print(f"Error: {e}")
```

```
Top 5 results:
  queen           similarity: 0.7118
  monarch         similarity: 0.6190
  princess        similarity: 0.5902
  crown_prince    similarity: 0.5499
  prince          similarity: 0.5377
```

```
# SEMANTIC SIMILARITY TEST 2: excellent ~ outstanding
try:
    similarity = pretrained_w2v.similarity('excellent', 'outstanding')
    print(f"\nSimilarity(excellent, outstanding) = {similarity:.4f}")

    # Show most similar words to 'excellent'
    print("\nWords most similar to 'excellent':")
    similar_words = pretrained_w2v.most_similar('excellent', topn=5)
    for word, score in similar_words:
        print(f"  {word:15} similarity: {score:.4f}")

except KeyError as e:
    print(f"Error: {e}")
```

```
Similarity(excellent, outstanding) = 0.5567

Words most similar to 'excellent':
  terrific        similarity: 0.7410
  superb          similarity: 0.7063
  exceptional     similarity: 0.6815
  fantastic       similarity: 0.6803
  good            similarity: 0.6443
```

(b) Custom Word2Vec — Trained on Amazon Office Product Reviews

We train a Word2Vec model from scratch on our preprocessed review corpus using Gensim's `Word2Vec` implementation.

Training hyperparameters:

Parameter	Value	Rationale
`vector_size`	300	Matches pretrained model for fair comparison
`window`	11	Wide context captures review-level co-occurrences
`min_count`	10	Filters rare words that lack reliable vector estimates
`sg`	1 (Skip-gram)	Better for rare/domain-specific words
`workers`	All CPU cores	Maximum training throughput

The resulting model vocabulary will be smaller than the pretrained model but tailored to product-review language (e.g., *defective*, *packaging*, *refund*, *shipper*).

```
# Prepare tokenized reviews for Word2Vec training
print("\nPreparing tokenized reviews...")
# Use your preprocessed reviews (already cleaned and lemmatized)
tokenized_reviews = [review.split() for review in df_balanced['review_body']]

print(f"Number of reviews: {len(tokenized_reviews):,}")
print(f"Sample tokenized review:")
print(f"  {tokenized_reviews[0][:20]}...")  # Show first 20 tokens
```

```
Preparing tokenized reviews...
Number of reviews: 250,000
Sample tokenized review:
  ['purchase', 'tab', 'whim', 'put', 'movie', 'poster', 'use', 'four', 'inch', 'tab', 'poster', 'not', 'job', 'poster', 'stay',
```

```
custom_w2v = Word2Vec(
    sentences=tokenized_reviews,
    vector_size=300,      # embedding size = 300
    window=11,            # window size = 11
    min_count=10,         # minimum word count = 10
    workers= multiprocessing.cpu_count(),            # use all available CPU cores
    seed=RANDOM_STATE,    # for reproducibility
    epochs=10,            # training epochs
```

```
    sg=0,                # CBOW (0) or Skip-gram (1)
    negative=5           # negative sampling
)

print("\nTraining complete!")

    words = review.split()
    for word in words:
        total_words += 1
        if word not in pretrained_w2v:
            oov_pretrained += 1
        if word not in custom_w2v.wv:
            oov_custom += 1

print(f"\n   Total words analyzed: {total_words:,}")
print(f"   Pretrained OOV rate: {oov_pretrained/total_words*100:.2f}%")
print(f"   Custom OOV rate: {oov_custom/total_words*100:.2f}%")
```

```
5. OUT-OF-VOCABULARY (OOV) ANALYSIS:
   Analyzing how many words from our reviews are missing from each model...

   Total words analyzed: 34,605
   Pretrained OOV rate: 3.13%
   Custom OOV rate: 2.95%
```

Analysis: Which Model Encodes Semantic Similarities Better?

Our five-metric comparison (vocabulary size, training data, domain vocabulary coverage, pairwise similarities, OOV rate) reveals complementary strengths:

Pretrained Word2Vec is better for **general semantic relationships:**

- Encodes broad analogies (*king – man + woman ≈ queen*) with high confidence.

- Captures general English word pairs (*good–excellent*, *bad–terrible*) with strong cosine similarity.
- Larger vocabulary (~3M words) means fewer OOV tokens for rare English words outside the product domain.

Custom Word2Vec is better for **domain-specific semantics:**

- Lower OOV rate on our review corpus (trained on the identical distribution).
- Better similarity scores for product-review terminology (*shipping*, *packaging*, *refund*, *defective*).
- Captures co-occurrence patterns specific to office product discussions that do not appear in news text.

Conclusion: The pretrained model is preferable for general-purpose NLP tasks; the custom model is preferable for sentiment analysis on product reviews. In downstream experiments (Q3–Q5), the custom embeddings consistently outperform pretrained ones.

Question 3: Baseline Classifiers with Word2Vec Features

Before training neural networks, we establish baseline performance using classical machine learning classifiers with averaged Word2Vec vectors as input features.

Feature extraction: Each review is represented as the **element-wise average** of all its word vectors, producing a single 300-dimensional vector regardless of review length. Words not found in the vocabulary are skipped.

Experimental setup:

Setting	Value
Task	Binary classification (Positive vs. Negative; neutral excluded)
Classifiers	Perceptron, SVM (linear kernel)
Embeddings	Pretrained (`word2vec-google-news-300`) and Custom
Train/Test split	80% / 20% (stratified)
Metric	Accuracy

```
def get_average_word2vec(review, model, is_custom=False):
    """
    Get the average Word2Vec vector for a review.

Q3 Results & Analysis

Model	Pretrained W2V	Custom W2V
Perceptron	69.25%	81.76%
SVM	83.38%	86.17%

Key findings:

1. **Best model:** SVM + Custom Word2Vec at **86.17%** accuracy.
2. **Custom > Pretrained** for both classifiers — domain-specific embeddings encode product-sentiment vocabulary more effectively than general news embeddings.
3. **SVM > Perceptron** — SVM's margin-maximizing objective handles the high-dimensional averaged vectors better than the Perceptron's simple linear threshold.
4. **Embedding quality matters most for simpler models:** Custom embeddings boost Perceptron accuracy by **+12.51%** but SVM by only **+2.79%**, showing that a stronger model (SVM) partially compensates for weaker features.
5. Both models trained on custom embeddings will serve as the lower-bound baselines for neural network comparisons in Q4 and Q5.

Question 4: Feed-Forward Neural Networks (FFNN)

We replace the baseline classifiers with a multi-layer feed-forward neural network and extend evaluation to include **ternary classification** (Positive, Negative, Neutral).

Architecture: `Linear(input) → ReLU → Linear(50) → ReLU → Linear(10) → ReLU → Linear(n_classes)`

Hyperparameter	Value
Hidden layers	2 (sizes 50, 10)
Activation	ReLU
Dropout	0.5
Optimizer	Adam (lr = 0.001)
Epochs	10
Batch size	32

We test two feature extraction strategies:

- **(a) Averaged vectors** — element-wise mean of all word embeddings → **300-dim** input
- **(b) Concatenated vectors** — first 10 word embeddings concatenated → **3,000-dim** input

Both strategies are evaluated on binary (2-class) and ternary (3-class) tasks using both pretrained and custom embeddings — **8 total experiments**.

(a) FFNN with Averaged Word2Vec Vectors

Input dimension: 300 (element-wise average of all word vectors in the review)

Rationale: Averaging over the full review provides a compact, fixed-size global representation. While it discards word order, it captures the aggregate semantic content of the entire review — particularly effective for longer reviews where the dominant sentiment pervades the whole text.

We train four variants: **Binary/Ternary** × **Pretrained/Custom embeddings**.

```

(b) FFNN with Concatenated Word2Vec Vectors

Input dimension: 3,000 (first 10 word embeddings × 300 dimensions each)

Rationale: Concatenating the first 10 word vectors preserves positional information and captures early-review cues. Reviews shorter than 10 words are zero-padded; reviews longer than 10 words are truncated — meaning only the first 10 tokens influence the prediction.

Trade-off vs. averaging:

- **Pro:** Retains some word-order information for early tokens.
- **Con:** Ignores the remainder of the review (most reviews are longer than 10 words), and introduces a much larger 3,000-dim input that increases the risk of overfitting with limited data.

We train four variants: **Binary/Ternary** × **Pretrained/Custom embeddings**.

```
def get_concatenated_word2vec(review, model, is_custom=False, max_words=10):
    """
    Get concatenated Word2Vec vectors for first 10 words.
    Pads with zeros if fewer than 10 words.

    Returns:
        3000-dimensional vector (10 words × 300 dims)
    """
    words = review.split()[:max_words]
    vectors = []

    for word in words:
        try:
            if is_custom:
                vec = model.wv[word]
            else:
                vec = model[word]
            vectors.append(vec)
        except KeyError:
            vectors.append(np.zeros(model.vector_size))

    while len(vectors) < max_words:
        vectors.append(np.zeros(model.vector_size))

    concatenated = np.concatenate(vectors)
    return concatenated

FFNN Concatenated - Ternary Custom: 0.6464
0
```

Q4 Results: Averaged vs. Concatenated Vectors

Classification	Q4(a) Averaged	Q4(b) Concatenated	Difference
Binary	87.28%	81.08%	**−6.20%**
Ternary	69.74%	64.73%	**−5.01%**

Analysis:

- **Averaged vectors consistently outperform concatenated vectors** on both binary and ternary tasks.
- The 6.20% binary accuracy gap confirms that using the full review context (averaging) is far more informative than restricting input to only the first 10 words.
- The 5.01% ternary gap follows the same pattern, suggesting that neutral reviews in particular benefit from global context to distinguish them from mild positive/negative sentiment.
- Ternary accuracy is ~17% lower than binary across both approaches, reflecting the inherent difficulty of classifying 3-star reviews that often contain mixed sentiment signals.

Question 5: Convolutional Neural Networks (CNN)

Convolutional neural networks capture **local n-gram patterns** in text by sliding learned filters across sequences of word vectors. Unlike FFNNs that treat the input as a flat bag-of-words, TextCNN preserves the sequential structure of reviews.

Architecture (`TextCNN`):

```
Input:  (batch, seq_len=50, embed_dim=300)
  │
  ├─ Conv1d(300→128, kernel=3)  →  ReLU  →  MaxPool1d
  │
  ├─ Conv1d(128→64, kernel=3)   →  ReLU  →  AdaptiveMaxPool1d(1)
  │
  ├─ Flatten  →  Dropout(0.5)
  │
  └─ Linear(64 → n_classes)
```

Input representation: Each review is converted to a fixed-length sequence of up to **50 word embeddings** (50 × 300 matrix). Reviews shorter than 50 words are zero-padded; longer reviews are truncated.

Evaluation: Binary and ternary classification using both pretrained and custom embeddings.

```
def reviews_to_sequences(reviews, model, max_length=50, is_custom=True):
    """
    Memory-efficient: Convert reviews to sequences using float32.

    Args:
        reviews: List or Series of review strings
        model: Word2Vec model
        max_length: Maximum sequence length (default 50)
        is_custom: Whether using custom Word2Vec

    Returns:
        numpy array of shape (num_reviews, max_length, 300) with dtype float32
```

```
    """
    vector_size = model.wv.vector_size if is_custom else model.vector_size

Homework 2 — Complete Results Summary

Q3: Baseline Classifiers (Averaged Word2Vec Features, Binary)

Model	Pretrained W2V	Custom W2V
Perceptron	69.25%	82.26%
SVM	83.38%	85.98%

Q4: Feed-Forward Neural Networks

Approach	Binary	Ternary
Q4(a) Averaged Vectors	87.28%	69.74%
Q4(b) Concatenated Vectors	81.08%	64.73%

Q5: Convolutional Neural Networks

Classification	Accuracy
Binary	88.57%
Ternary	70.91%

Overall Best Models

Task	Best Model	Accuracy
Binary	CNN (Q5)	**88.57%**
Ternary	CNN (Q5)	**70.91%**

Key Insights

1. **CNNs achieve the highest accuracy** on both tasks by capturing local sequential patterns (trigrams, positional context) that carry strong sentiment signals — something averaged or concatenated vectors cannot exploit.
2. **Averaged word vectors outperform concatenated** vectors across all FFNN experiments (+6.2% binary, +5.0% ternary). Using the complete review context is far more informative than truncating to the first 10 words.
3. **Custom Word2Vec outperforms pretrained embeddings** for our domain. The vocabulary overlap with office-product review language reduces OOV rates and improves feature quality, boosting Perceptron by +12.5% and SVM by +2.8%.
4. **Neural networks outperform classical classifiers** by approximately 2–3% on binary classification (CNN: 88.57% vs. SVM: 85.98%), demonstrating the benefit of learned non-linear representations.
5. **Ternary classification is consistently harder** than binary — all models score 15–20% lower. Three-star (neutral) reviews contain genuinely mixed sentiment that is difficult to distinguish from weakly positive or weakly negative reviews.
